STAT 333 Course Note

Table of Contents

1. Fundamental of Probability

1.1 What's Probability

1.1.1 Examples

1. Coin toss
   - "H" - head
   - "T" - tail
2. Roll a dice
   - every number in the set: $\{1, 2, 3, 4, 5, 6\}$
3. Tomorrow weather
   - {sunny, rainy, cloudy,...}
4. Randomly pick a number in $[0, 1]$

Although things are random, they are not haphazard/arbitrary. There are "patterns"

Example 1

If we repeat tossing a coin, then the fraction of times that we get a "H" goes to $\frac{1}{2}$ as the number of toss goes to infinity.

$$\frac{\#\text{ of "H"}}{\text{total }\#\text{ of toss}} = \frac{1}{2}$$

This number $\frac{1}{2}$ reflects how "likely" a "H" will appear in one toss (Even if the experiment is not repeated)

1.2 Probability Models

The *Sample space* Ω is the set consisting of al the possible outcomes of a random experiment.

1.2.1 Examples

1. $\{H, T\}$
2. $\{1, 2, 3, 4, 5, 6\}$
3. $\{sunny, rainy, cloudy, ...\}$
4. $[0, 1]$

An *event* $E \in \Omega$ is a subset of Ω

for which we can talk about "likelihood of happening"; for example

- in **2**:
  - {getting an even number} = {2, 4, 6}
- in **4**:
  - $\{the\ point\ is\ between\ 0\ and\ 1/3\} = [0, \frac{1}{3}]$ is an event
  - $\{the\ point\ is\ rational\} = Q \cap [0, 1]$

We say an even E "happens", if the result of the experiment turns out to belong to E (a subset of Ω)

A probability P is a set function (a mapping from events to real numbers)

$$\begin{aligned} P :&\xi \to R \\ &E \to P(E) \end{aligned}$$

which satisfies the following 3 properties:

1. $\forall E \in \xi, 0 \leq P(E) \leq 1$
2. $P(\Omega) = 1$
3. For
    - countably many disjoint events $E_1, E_2, ...$, we have $P(U_{i=1}^{\infty} E_i) = \sum_{i=1}^{\infty} P(E_i)$
    - countable: $\exists$ 1-1 mapping to natural numbers $1, 2, 3, ...$

Intuitively, one can think the probability of an event as the "likelihood/chance" for the event happens. If we repeat the experiment for a large number of events, the probability is the fraction of time that the event happens

$$P(E) = \lim_{n \to \infty} \frac{\#\text{ of times the E happens in n trials}}{n}$$

1.2.1.1 Example 2

$$\begin{aligned} &P(\{1\}) = P(\{2\}) = \ldots = P(\{6\}) = \frac{1}{6} \\ &E = \{\text{even number}\} = \{2, 4, 6\} \\ \Rightarrow\ &P(E) = P(\{2\} \cup P(\{4\})) \cup P(\{6\}) = \frac{1}{2} \end{aligned}$$

Properties of probability:

1. $P(E) + P(E^c) = 1$
2. $P(\emptyset) = 0$
3. $E_1 \subseteq E_2 \Rightarrow P(E_1) \leq P(E_2)$
4. $P(E_1 \cup E_2) = P(E_1) + P(E_2) - P(E_1 \cap E_2)$
    - $P(E_1 \cap E_2)$: E_1 and E_2 happen

1.2.2 Remark: why do we need the notion of event?

If the sample space Ω is **discrete**, then everything can has at most countable elements be built from the "atoms"

$$\begin{aligned} \Omega &= \{w_1, w_2, \ldots\} \\ P(w_1) &= P_i \\ P_i \in [0, 1], &\sum_{i=1}^{\infty} P_i = 1 \end{aligned}$$

Then for any event $E = \{w_1, i \in I\}$, $P(E) = \sum_{i \in I} P_i$

However, if the sample space Ω is continuous; e.g, $[0, 1]$ in Example 4, then such a construction can not be done for any $x \in [0, 1]$ we get $P(\{x\} = 0$ (x: the point is exactly x)

We can not get $P([0, \frac{1}{3}])$ by adding $P(\{x\})$ for $x \leq \frac{1}{3}$.

This is why we need the notion of event; and we define P as a set function from ξ to R rather than a function from Ω to R

To summarize: A **Probability Space** consists of a triplet (Ω, ξ, P):

- Ω: sample space,
- ξ: collection of events
- P: probability

1.3 Conditional Probability

If we know some information, the probability of an event can be updated

Let E, F be two events $P(F) > 0$

The conditional probability of E, given F is

$$P(E \mid F) = \frac{P(E \cap F)}{P(F)}$$

Again, think probability as the long-run frequency:

$$\begin{aligned} P(E \cap F) &= \lim_{n \to \infty} \frac{\#of\ times\ E\ and\ F\ happen\ in\ n\ trails}{n} \\ P(F) &= \lim_{n \to \infty} \frac{\#of\ times\ F\ happen\ in\ n\ trails}{n} \\ \Rightarrow \frac{P(E \cap F)}{P(F)} &= \lim_{n \to \infty} \frac{\#of\ times\ E\ and\ F\ happen}{\#of\ times\ F\ happens} \end{aligned}$$

By definition

$$P(E \cap F) = P(E \mid F) \cdot P(F)$$

1.4 Independence

Def: Two events E and F are said to be independent, if $P(E \cap F) = P(E) \cdot P(F)$; denoted as $E \perp\!\!\!\perp F$. **This is different rom disjoint.**

Assume $P(F) > 0$, then $E \perp\!\!\!\perp F \Leftrightarrow P(E|F) = P(E)$; intuitively, knowing F does not change the probability of E.

Proof:

$$\begin{aligned} E \perp\!\!\!\perp F &\Leftrightarrow P(E \cap F) = P(E) \cdot P(F) \\ &\Leftrightarrow \frac{P(E \cap F)}{P(F)} = P(E) \\ &\Leftrightarrow P(E|F)) = P(E) \end{aligned}$$

More generally, a sequence of events $E_1, E_2, \ldots$ are called independent if for **any** finite index set I,

$$P(\bigcap_{i \in I} E_i) = \prod_{i \in I} P(E_i)$$

1.5 Bayes' rule and law of total probability

Theorem: Let $F_1, F_2, \ldots$ be disjoint events, and $\bigcap_{i=1}^{\infty} F_i = \Omega$, we say $\{F_u\}_{i=1}^{\infty}$ forms a "partition" of the sample space Ω

Then $P(E) = \sum_{i=1}^{\infty} P(E|F_i) \cdot P(F_i)$

Proof: Exercise

Intuition: Decompose the total probability into different cases.

$$P(E \cap F_2) = P(E|F+2) \cdot P(F_2)$$

1.5.1 Bayes' rule

$$P(F_i|E) = \frac{P(E|F_i) \cdot P(F_i)}{\sum_{h=1}^{\infty} P(E|F_j) \cdot P(F_j)}$$

Bayes' rule tells us how to find conditional probability by switching the role of the event and the condition.

Proof:

$$\begin{aligned} P(F_i|E) &= \frac{P(F_i \cap E)}{P(E)} && \text{definition of condition probability} \\ &= \frac{P(E|F_i)P(F_i)}{P(E)} \\ &= \frac{P(E|F_i)P(F_i)}{\sum_{j=1}^{\infty} P(E|F_j)P(F_j)} && \text{law of total probability} \end{aligned}$$

2 Random variables and distributions

2.1 Random variables

(Ω, ξ, P): Probability space.

Definition: A random variable X (or r.v.) is a mapping from Ω to $\mathbb{R}$

$$\begin{aligned} X :& \Omega \to \mathbb{R} \\ & \omega \to X(\omega) \end{aligned}$$

A random variable transforms arbitrary "outcomes" into numbers.

X introduces a probability on R. For $A \subseteq R$, define

$$\begin{aligned} P(X \in A) :&= P(\{X(\omega) \in A\}) \\ &= P(\{\omega : X(\omega) \in A\}) \\ &= P(X^{-1}(A)) \end{aligned}$$

From now on, we can often "forget" te original probability space and focus on the random variables and their distributions.

Definition: let X be a random variable. The **CDF**(cumulative distribution function) F of X is defined by

$$\begin{gathered} F(x) = P(X \leq x) = P(X \in (-\infty, x])) \\ X : \text{random variable}, x : \text{number} \end{gathered}$$

Properties of cdf:

1. F is non-decreasing. $F(x_1) \leq F(x_2), x_1 < x_2$
2. limits
    - $\lim_{x \to -\infty} F(x) = 0$
    - $\lim_{x \to \infty} F(x) = 1$
3. $F(x)$ is right continuous
    - $lim_{x \downarrow a} F(x) = F(a)$: x decreases to a(approaching from the right)
    - Hint: $\{x \leq a\} = \bigcap_{i=1}^{\infty} \{X \leq a_i\}$ for $a_i \downarrow a$

2.2 Discrete random variables and distributions

A random variable X is called **discrete** if it only takes values in an **at most countable** set $\{x_1, x_2, \ldots\}$ (finite or countable).

The distribution of a discrete random variable is fully characterized by its **probability mass function**(p.m.f)

$$p(x) := P(X = x); x = x_1, x_2, \ldots$$

Properties of pmf:

1. $p(x) \geq 0, \quad \forall x$
2. $\sum_i p(x_i) = 1$

Q: what does the cdf of a discrete random variable look like?

2.2.1 Examples of discrete distributions

1. Bemoulli distribution

$$\begin{aligned} p(1) &= P(X = 1) = p \\ p(c) &= P(X = c) = 1 - p \\ p(x) &= 0 otherwise \end{aligned}$$

Denote $X \sim Ber(p)$

2.Binomial distribution

$$p(k) = P(X = k) = \binom{n}{k} p^k (1-p)^{n-k}$$

- $X \sim Bin(n, p)$ to choose k successes.
- Binomial distribution is the distribution of number of successes in n independent trials; each having probability p of sucess.

3.Geometric distribution

$$p(k) = P(X = k) = (1-p)^{k-1} p$$

$$(1-p)^{k-1} : \text{the first k-1 trials are all failures}, \quad p : \text{success in } k^{th} \text{ trial}$$

- $X \sim Geo(p)$
- X is the number of trials needed to get the first success in n independent trials with probability p of success each
- X has the memoryless property $P(X > n + m | X > m) = P(x > n) \qquad n, m = 0, 1, \ldots$

Memoryless property:

$$p(X > n+m|X > m) = P(X > n)a$$

Proof:

$$\begin{aligned} P(X > k) &= \sum_{j=k+1}^{\infty} P(X = j) \\ &= \sum_{j=k+1}^{\infty} (i-p)^{j-1}p \\ &= (1-p)^k p \cdot \frac{1}{1-(1-p)} \\ &= (1-p)^k \\ P(X > n+m|x > m) &= \frac{P(X > n+m), X > m}{P(X > m)} \\ &= \frac{P(X > n+m)}{P(X > m)} = \frac{1-p)^{n+m}}{(1-p)^m} = (1-p)^n = P(X > n) \end{aligned}$$

Intuition: The failures in the past have no influence on how long we still need to wait to get the first success in the future

4. Poisson distribution

$$p(k) = P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!}, k = 0, 1, 2, \ldots, \lambda > 0$$

Other discrete distributions:

- negative binomial
- discrete uniform

2.3 Continuous random variables and distributions

Definition: A random variable X is called **continuous** if there exists a non-negative function f, such that for any interval $[a, b]$, (a, b) or $[a, b)$:

$$P(X \in [a, b]) = \int_a^b f(x)dx$$

The function f is called the *probability density function(pdf)* of X

Remark: probability density function(pdf) is not probability. $P(X = x) = 0$ if X is continuous. The probability density function f only gives probability when it is integrated.

If X is continuous, then we can get cdf by:

$$F(a) = P(X \in (-\infty, a]) = \int_{\infty}^a f(x)dx$$

hence, $F(x)$ is continuous, and differentiable "almost everywhere".

We can take $f(x) = F'(x)$ when the derivative exists, and $f(x) =$arbitrary number otherwise often to choose a value to make f have some continuity.

Property of pdf:

1. $f(x) \leq 0, x \in R$
2. $\int_{-\infty}^{\infty} f(x)dx = 1$
3. For $A \subseteq R, P(X \in A) = \int_A f(x)dx$

2.3.1 Example of continuous distribution

Exponential distribution

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & , x \geq 0 \\ 0 & , x \leq 0 \end{cases}$$
$$X \sim Exp(x)$$

Other continuous distributions:

- Normal distribution
- Uniform distribution

Exercises:

1. Find the cdf of $X \sim Exp(x)$
2. Show that the exponential distribution has the memoryless property:

$$P(X > t + s | x > t) = P(X > s)$$

2.4 Joint distribution of r.v's

Let X and Y be two r.v's. defined on the same probability space (Ω, ξ, P)

For each $\omega \in \Omega$, we have at the same time $X(\omega)$ and $Y(\omega)$. Then we can talk about the joint behavior of X and Y

Two joint distribution of r.v's is characterized by joint cdf, joint pmf(discrete case) or joint pdf(continuous case).

- Joint cdf:
  - $F(x, y) = P(X < x, Y < y)$
- Joint pmf:
  - $f(x, y) = P(X = x, Y = y)$
- joint pdf $f(x, y)$ such that for $a < b, c < d$
  - $P(X, Y) \in (a, b] \times (c, d] = P(X \in (a, b], Y \in (c, d]) = \int_a^b \int_c^d f(x, y)dydx$
  - Equivalently:
    1. $F(x, y) = \int_{-\infty}^{x} \int_{-\infty}^{y} f(s, t)dtds$
       $f(x, y) = \frac{\partial^2}{\partial x \partial y} F(x, y)$
    2. $P((X, Y) \in A) = \int \int_A f(x, y)dxdy$ for $A \subseteq R^2$

Definition: Two r.v's X and Y are called independent, if for all sets $A, B \subseteq R$,

$$P(X < A, Y < B) = P(X \in A)P(Y \in B)$$

($\{X \in A\}$ and $\{Y \in B\}$ are independent events)

Theorem: Two r.v's X and Y are

1. independent, if and only if
2. $F(x,y) = F_x(x)F_y(y); x,y \in R$; where F_x: cdf of x; F_y: cdf of y
3. $f(x,y) = f_x(x)f_y(y); x,y \in R$; where f is the joint pmf/pdf of X and Y; f_x, f_y are marginal pmf/pdf of X and Y, respectively

Proof:

1.$\Rightarrow$ 2.

If $X \perp Y$, then by definition,

$$F(x,y) = P(X \in (-\infty, x], Y \in (-\infty, y])) = P(X \in (-\infty, x])) \cdot P(Y \in (-\infty, y])) = F_x(x)F_y(y)$$

2.$\Rightarrow$ 3.

Assume $F(x,y) = F_x(x) \cdot F_y(y)$,

$$\begin{aligned} f(x,y) = \frac{\partial^2}{\partial x \partial y} F(x,y) &= \frac{\partial^2}{\partial x \partial y} F_x(x)F_y(y) \\ &= (\frac{\partial}{\partial x} F_x(x))(\frac{\partial}{\partial y} F_y(y)) \\ &= f_x(x)f_y(y) \end{aligned}$$

3.$\Rightarrow$ 1.

Assume $f(x,y) = f_x(x)f_y(y)$; For $A, B \subseteq R$,

$$\begin{aligned} P(X \in A, Y \in B) &= \int_{y \in B} \int_{x \in A} f(x,y) dx dy \\ &= \int_{y \in B} \int_{x \in A} f_x(x) f_y(y) dx dy \\ &= (\int_{x \in A} f_x(x) dx)(\int_{y \in B} f_y(y) dy) \\ &= P(X \in A) P(Y \in B) \end{aligned}$$

2.5 Expectation

Definition: For a r.v X, the expectation of $g(x)$ is defined as

$$\exists(g(x)) = \begin{cases} \sum_{i=1}^{\infty} g(x_i) P(X = x_i) & \text{for discrete } X \\ \int_{-\infty}^{\infty} g(x) f(x) dx & \text{for continuous} X \end{cases}$$

Let X,Y be two r.v's; then the expectation of $g(X,Y)$ is defined in a similar way.

$$\exists(g(x,y)) = \begin{cases} \sum \sum g(x_i, y_j) P(X = x_i, Y = y_j) \\ \int \int g(x_i, y_j) f(x,y) dx dy \end{cases}$$

2.5.1 Properties of expectation

1. Linearity:expectation of X: $\mathbb{E}(X) = \begin{cases} \sum X_i \mathbb{P}(X = x_i) \\ \int_{-\infty}^{x_1} x f(x) dx \end{cases}$, $g(X) = x$
    - $\mathbb{E}(ax + b) = a\mathbb{E}(x) + b$
    - $\mathbb{E}(X + Y) = \mathbb{E}(X) + \mathbb{E}(Y)$
2. If $X \perp\!\!\!\perp Y$, then $\mathbb{E}(g(X)h(Y)) = \mathbb{E}(g(X)) \cdot \mathbb{E}(h(Y))$
    - **proof**: (continuous case)
    - $$\begin{aligned} \mathbb{E}(g(X)h(Y)) &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x)h(y)f(x,y)dxdy \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x)h(y)f_X(f)f_Y(y)dxdy \\ &= \int_{-\infty}^{\infty} g(x)f_X(x) \cdot \int_{-\infty}^{\infty} h(y)f_Y(y)dy \end{aligned}$$
    - In particular, $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$ if $X \perp\!\!\!\perp Y$

2.5.2 Definitions

Definition: The expectation $\mathbb{E}(X^n)$ is called the n-th moment of X:

- 1st moment: $\mathbb{E}(X)$
- 2st moment: $\mathbb{E}(X^2)$

Definition: The variance of a r.v X is defined as:

$$Var(x) = \mathbb{E}((X - \mathbb{E}(X))^2) \text{ also denoted as } \sigma^2, \sigma_x^2$$

Definition: the covariance of the r.v's X and Y is defined as:

$$Cov(X, Y) = \mathbb{E}((X - \mathbb{E}(X)))\mathbb{E}((Y - \mathbb{E}(Y)))$$

Thus $Var(X) = Cov(X, X)$

Definition: the correlation between X and Y is defined as:

$$Cor(X, Y) = \frac{Cov(X, Y)}{\sqrt{Var(X)Var(Y)}}$$

Fact: $Var(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2$

Proof:

$$\begin{aligned} Var(X) &= \mathbb{E}((X - \mathbb{E}(X))^2) \\ &= \mathbb{E}(X^2 - 2X\mathbb{E}(X) + (\mathbb{E}(X)^2)) \\ &= \mathbb{E}(X^2) - 2\mathbb{E}(X\mathbb{E}(X)) + (\mathbb{E}(X))^2 \\ &= \mathbb{E}(X^2) - 2(\mathbb{E}(X))^2 + (\mathbb{E}(X))^2 \\ &= \mathbb{E}(X^2) - (\mathbb{E}(X))^2 \end{aligned}$$

Fact: $Cov(X, Y) = \mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y)$

Proof: similar to previous

Variance and covariance are **translation invariant**. Variance is quadratic, covariance is bilinear.

$$Var(aX+b) = a \cdot Var(X)$$

$$Cov(aX+b, cY+d) = ac \cdot Cov(X,Y)$$

Proof:

$$\begin{aligned} Var(aX+b) &= \mathbb{E}((aX+b0\mathbb{E}(aX+b)^2)) \\ &= \mathbb{E}([a(X-\mathbb{E}(X))]^2) \\ &= a^2\mathbb{E}((X-\mathbb{E}(X)^2)) \\ &= a^2\mathbb{E}(X) \end{aligned}$$

Proof: $Var(X+Y) = Var(X) + Var(Y) + 2Cov(X,Y)$

Exercise

If $X \perp\!\!\!\perp Y$, then $Cov(X,Y) = 0$ and $Var(X+Y) = Var(X) + Var(Y)$

Proof:

$$\begin{aligned} &Cov(X,Y) = \mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y) \\ &\text{we know:} \\ &X\ Y \Rightarrow \mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y) \\ &\text{Thus, } Cov(X,Y) = 0 \Rightarrow Var(X+Y) = Var(X) + Var(Y) + 2Cov(X,Y) \\ &\text{So we see independence} \Rightarrow \text{Covariance is 0: "uncorrelated"} \\ &\text{the converse is not true.} \\ &Cov(X,Y) = 0 \Rightarrow \not{}\text{independence} \end{aligned}$$

Remarks

We have $\mathbb{E}(X+Y) = \mathbb{E}(X) + \mathbb{E}(Y)$.

If $X \perp\!\!\!\perp Y$, we also have:

- $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$, and
- $Var(X+Y) = Var(X) + Var(Y)$

It's important to remember that the first result and the other two results are of very different nature. While $\mathbb{E}(X+Y) = \mathbb{E}(X) + \mathbb{E}(Y)$ is a property of expectation and holds unconditionally;

the other two, $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$ and $Var(X+Y) = Var(X) + Var(Y)$, only hold if $X \perp\!\!\!\perp Y$.

It is more appropriate to consider them as **properties of independence** rather than properties of expectation and variance

2.6 Indicator

A random variable I is called an indicator, if

$$I(w) = \begin{cases} 1 & \omega \in A \\ 0 & \omega \in \not{}A \end{cases}$$

$$P(I_A) = P(A)$$

for some event A

For A given, I is also elevated as I_A

The most important property of indicator is its expectation gives the probability of the event $\mathbb{E}(I_A) = \mathbb{P}(A)$

Proof:

$$\begin{aligned}\mathbb{P}(I_A = 1) &= \mathbb{P}(\omega : I_A(\omega = 1)) \\ &= \mathbb{P}(\omega : \omega \in A) \\ &= \mathbb{P}(A)\end{aligned}$$

$$\mathbb{P}(I_A = 0) = 1 - \mathbb{P}(A) \Rightarrow \mathbb{E}(I_A) = 1 \cdot \mathbb{P}(A) + c \cdot (1 - \mathbb{P}(A)) = \mathbb{P}(A)$$

2.6.1 Example

we see $I_A \sim Ber(\mathbb{P}(A))$

Let $X \sim Bin(n, p)$, X is number of successes in n Bernoulli trials, each with probability p of success

$$\Rightarrow X = I_1 + \cdots + I_n$$

where $I_1, \cdots, I_n$ are indicators for independent events. $I_i = 1$ if th i the trial is a success. $I_i = 0$ if the i th trial is a failure.

Hence I_i are **i.d.**(independent and identically distributed) r.v's

$$\begin{aligned}\Rightarrow \mathbb{E}(X) &= \mathbb{E}(I_1 + \cdot, I_N) \\ &= \mathbb{E}(I_1) + \cdots | \mathbb{E}(I_n) \\ &= p + \cdots + p = n \cdot p\end{aligned}$$

$$\begin{aligned}Var(X) &= Var(I_1 + \cdots + I_n) \\ &= Var(I_1) + \cdots + Var(I_n) \\ &= n \cdot Var(I_i) \\ &= n \cdot p(1 - p)\end{aligned}$$

$$Var(I_1) = \mathbb{E}(I_1^2) - (\mathbb{E}(I_1))^2 = \mathbb{E}(I_1) - (\mathbb{E}(I_1))^2 = p - p^2 = p(1 - p)$$

2.6.1 Example 3

Let X be a r.v. taking values in non-negative integers, then

$$\mathbb{E}(X) = \sum_{n=0}^{\infty} P(X > n)$$

Proof:

Note that $X = \sum_{n=0}^{\infty} I_n$ where $I_n = I_{x>n}$. ($x > n$ is an event)

$$\begin{aligned}\mathbb{E}(X) &= \mathbb{E}(\sum_{n=0}^{\infty} I_n) \\ &= \sum_{n=0}^{\infty} \mathbb{E}(I_n) \\ &= \sum_{n=0}^{\infty} P(X > n)\end{aligned}$$

In particular, let $X \sim Geo(p)$. As we have seen, $P(X > n) = (1-p)^n \Rightarrow$

$$\begin{aligned}\mathbb{E}(X) &= \sum_{n=0}^{\infty} P(X > n) \\ &= \sum_{n=0}^{\infty} (1-p)^n \\ &= \frac{1}{1-(1-p)} = \frac{1}{p}\end{aligned}$$

2.7 Moment generating function

Definition: Let X be a r.v. Then the function $M(t) = \mathbb{E}(e^{tx})$ is called the *moment generating function(mgf)* of X, if the expectation exists for all $t \in (-h, h)$ for some $h > 0$.

Remark: The mgf is not always well-defined. It is important to check the existence of the expectation.

2.7.1 Properties of mgf

1. Moment Generating Function generates moments
    - **Theorem**:
        - $M(0) = 1$
        - $M^{(k)}(0) = \mathbb{E}(X^k), k = 1, 2, \dots$ ($M^{(k)} = \frac{d^k}{dt^k} M(t)|_{t=0}$)
            - **Proof**:

$$\begin{aligned}M(0) &= \mathbb{E}(e^{0 \cdot X}) = \mathbb{E}(1) = 1 \\ M^{(k)}(0) &= \frac{d^k}{dt^k} \mathbb{E}(e^{t \cdot X})|_{t=0} \\ &= \mathbb{E}(\frac{d^k}{dt^k} e^{tX}|_{t=0}) \\ &= \mathbb{E}(X^k)\end{aligned}$$

        - As a result, we have: $M(t) = \sum_{k=0}^{\infty} \frac{M^{(k)}(0)}{k!} t^k = \sum_{k=0}^{\infty} \frac{E * X^k}{k!} t^k$ (a method to get moment of a r.v)
2. $X \perp\!\!\!\perp Y$, with mgf's M_x, M_y. Let M_{X+Y} be the mgf of $X + Y$. then

$$M_{X+Y}(t) = M_X(t) M_Y(y)$$

    - **Proof**:

$$\begin{aligned} M_{X+Y}(t) &= \mathbb{E}(e^{t(X+Y)}) \\ &= \mathbb{E}(e^{tx}e^{ty}) \\ &= \mathbb{E}(e^{tx})\mathbb{E}(e^{ty}) \\ &= M_X(y)M_Y(t) \end{aligned}$$

3. The mgf completely determines the distribution of a r.v.
    - $M_X(t) = M_Y(t)$ for all $t \in (-h, h)$ for some $h > 0$, then $X \overset{d}{=} Y$. ($\overset{d}{=}$: have the smae distribution)
    - Example: Let $X \sim Poi(\lambda_1)$, $Y \sim Poi(\lambda_2)$. $X \perp\!\!\!\perp Y$. Find the distribution of $X + Y$

        - First, derive the mgf of a Poisson distribution.

$$\begin{aligned} M_X(t) &= \mathbb{E}(e^{tX}) \\ &= \sum_{n=0}^{\infty} e^{tn} \cdot P(X = n) \\ &= \sum_{n=0}^{\infty} e^{tn} \cdot \frac{\lambda_1^n}{n!} e^{-\lambda_1} \\ &= \sum_{n=0}^{\infty} \frac{(e^t \cdot \lambda_1)^n}{n!} \cdot e^{-\lambda_1} \end{aligned}$$

$$\text{we know that } \sum_{n=0}^{\infty} \frac{(e^t\lambda_1)^n}{n!} = e^{e^t \cdot \lambda_1}. (\text{Since } \frac{(e^t\lambda_1^n)}{n!} e^{-e^t\lambda_1} \text{ is the pmf of } Poi(e^t\lambda_1))$$

$$\Rightarrow M_X(t) = e^{e^t\lambda_1}e^{-\lambda_1} = e^{\lambda_1(e^t-1)}, t \in \mathbb{R}. (e^{\lambda_1(e^t-1)} \text{ is mgf of } Poi(\lambda_1))$$

$$\text{Similarly, } M_Y(t) = e^{\lambda_2(e^t-1)}.$$

We know that

$$\begin{aligned} M_{X+Y}(t) &= M_X(t)M_Y(t) \\ &= e^{\lambda_1(e^t-1)}e^{\lambda_2(e^-1)} \\ &= e^{(\lambda_1+\lambda_2)(e^t-1)} \end{aligned}$$

This is the mgf of $Poi(\lambda_1 + \lambda_2)$!

Since the mgf uniquely determines the distribution $X + Y \sim Poi(\lambda_1 + \lambda_2)$

In general, if $X_1, X_2, \ldots, X_n$ independent, $X_i \sim Poi(\lambda_i)$, then $\sum X_i \sim Poi(\sum \lambda_i$

2.7.2 Joint mgf

Definition: Let X, Y be r.v's. Then $M(t_1, t_2) := \mathbb{E}(e^{t_1X+t_2Y}$ is called the joint mgf of X and Y, if the expectation exists for all $t_1 \in (-h_1, h_1)$, $t_2 \in (-h_2, h_2)$ for some $h_1, h_2 > 0$.

More generally, we can define $M(t_1, \ldots, t_n) = \mathbb{E}(exp(\sum_{i=1}^n t_iX_i))$ for r.v's $X_1, \cdots, X_n$, if the expectation exists for $\{(t_1, \cdots, t_n) : t_i \in (-h_i, h_i), i = 1, \cdots, n\}$ for some $\{h_i > 0\}, i = 1, \cdots, n$

2.7.2.1 Properties of the joint mgf

1. $$\begin{aligned} M_X(t) &= \mathbb{E}(e^{tX}) \\ &= \mathbb{E}(e^{tX+oY}) \\ &= M(t,o) \\ M_Y(t) &= M(o,t) \end{aligned}$$

2. $$\frac{\partial^{m+n}}{\partial t_1^m \partial t_2^n} M(t_1,t_2)|_{(0,0)} = \mathbb{E}(X^m Y^n$$
$$\text{the proof is similar to the single r.v. case}$$

3. If $X \perp\!\!\!\perp Y$, then $M(t_1,t_2) = M_X(t_1)M_Y(t_2)$
   - **Proof**:

$$\begin{aligned} M(t_1,t_2) &= \mathbb{E}(e^{t_1X+t_2Y}) \\ (X \perp\!\!\!\perp Y) &= \mathbb{E}(e^{t_1X}e^{t_2Y}) \\ &= \mathbb{E}(e^{t_1X}) \cdot \mathbb{E}(e^{t_2Y}) \\ &= M_X(t_1) \cdot M_Y(t_2) \end{aligned}$$

   - **Remark**: Don't confuse this with the result $X \perp\!\!\!\perp Y \Rightarrow M_{X+Y}(t) = M_X(t)M_Y(t)$.
     - $M_{X+Y}(t) \rightarrow$ mgf of $X+Y$; single argument function t
     - $M(t_1,t_2) \rightarrow$ joint mgf of (X,Y); two arguments t_1, t_2

3. Conditional distribution and conditional expectation

3.1 Conditional distribution

3.1.1 Discrete case

Definition Let X and Y be discrete r.v's. The conditional distribution of X given Y is given by:

$$P(X=x|Y=y) = \frac{(P(X=x,Y=u))}{P(Y=y)}$$

$$P(X=x|Y=y) : f_{X|Y} = y(x), f_{X|Y}(x|y) \leftarrow \text{conditional probability mass function})$$

Conditional pmf is a legitimate pmf: given any y, $f_{X|Y=y}(x) \geq 0, \forall x$

$$\sum_x f_{X|Y=y}(x) = 1$$

Note that given $Y=y$, as x changes, the value of the function $f_{X|Y=y}(x)$ is proportional to the joint probability.

$$f_{X|Y=y}(x) \propto P(X=x,Y=y)$$

This is useful for solving problems where the denominator $P(Y=y)$ is hard to find.

3.1.1.1 Example

$X_1 \sim Poi(\lambda_1), X_2 \sim Poi(\lambda_2)$. $X_1 \perp\!\!\!\perp X_2$, $Y = X_1 + X_2$

Q: $P(X_1 = k|Y=n)$?

Note $P(X_1=k|Y=u) = f_{X_1|Y=n}(k)$

A: $P(X_1 = k|Y = n)$ can only be non-zero for $k = 0, \cdots, n$ in this case,

$$\begin{aligned} P(X_1 = k|Y = n) &= \frac{P(X_1 = k, Y = n)}{P(Y = n)} \\ &\propto P(X_1 = k, Y = n) \\ &= P(X_1 = k, X_2 = n - k) \\ &= e^{-\lambda_1} \frac{\lambda_1^k}{k!} \cdot e^{-\lambda_2} \frac{\lambda_2^{n-k}}{(n-k)!} \\ &\propto (\frac{\lambda_1}{\lambda_2})^k / k!(n-k)! \end{aligned}$$

we can get $P(X = k|Y = n)$ by normalizing the above expression.

$$P(X_1 = k, Y = n) = \frac{(\frac{\lambda_1}{\lambda_2})^k / k!(n-k)!}{\sum_{k=0}^{n} (\frac{\lambda_1}{\lambda_2})^k / k!(n-k)!}$$

but then we will need to fine $\sum_{k=0}^{n} (\frac{\lambda_1}{\lambda_2})^k / k!(n-k)!$

An easier way is to compare $\sum_{k=0}^{n} (\frac{\lambda_1}{\lambda_2})^k / k!(n-k)!$ with the known results for common distribution. In particular, if $X \sim Bin(n, p)$

$$\begin{aligned} P(X = k) &= (\overset{n}{k}) p^k (1-p)^{n-k} \\ &\propto (\frac{p}{1-p})^k / k!(n-k)! \end{aligned}$$

$\Rightarrow P(X_1 = k|Y = n)$ follows a binomial distributions with parameters n and p given by $\frac{p}{1-p} = \frac{\lambda_1}{\lambda_2} \Rightarrow p = \frac{\lambda_1}{\lambda_1 + \lambda_2}$

Thus, given $Y = X_1 + X_2 = n$, the conditional distribution of X_1 is binomial with parameter n and $\frac{\lambda_1}{\lambda_1 + \lambda_2}$

3.1.2 Continuous case

Definition: Let X and Y be continuous r.v's. The conditional distribution of X given Y is given by

$$f_{X|Y}(x|y) = f_{X|Y=y}(x) = \frac{f(x, y)}{f_Y(y)}$$

A conditional pdf is a legitimate pdf

$$\begin{aligned} f_{X|Y}(x|y) &\geq 0 \qquad\qquad x, y \in \mathbb{R} \\ \int_{-\infty}^{\infty} f_{X|Y}(x|y) dx &= 1, \quad y \in \mathbb{R} \end{aligned}$$

3.1.2.1 Example

Suppose $X \sim Exp(\lambda)$, $Y|X = x \sim Exp(x) = f_{Y|X}(y|x) = xe^{-xy}, y = e \leftarrow$ conditional distribution of Y given $X = x$

Q: Find the condition pdf $f_{X|Y}(x|y)$

A:

$$
\begin{aligned}
f_{X|Y}(x|y) &= \frac{f(x,y)}{f_Y(y)} \\
&\propto f(x,y) \\
&= f_{Y|X}(y|x) \cdot f_X(x) \\
&= xe^{xy}\lambda e^{-\lambda x a} \\
&\propto xe^{-x(y+\lambda)}, \qquad x>0, y>0
\end{aligned}
$$

Normalization (make the total probability 1)

$$
f_{X|Y}(x|y) = \frac{xe^{-x(y+\lambda)}}{\int_0^\infty xe^{-x(y+\lambda)}dx}
$$

$$
\int_0^\infty xe^{-x(y+\lambda)}dx = \frac{1}{\lambda+t}^2 \leftarrow \text{integration by parts}
$$

Thus, $f_{X|Y}(x|y) = (\lambda+y)^2 xe^{-x(y+\lambda)}$, $x>0$.

This is a gamma distribution with parameters γ and $\lambda+y$

3.1.2.1. Example 2

Find the distribution of $z=XY$.

Attention: the following method is wrong:

$$
f_Z(z) = \int_0^\infty f_{Y|X}(\frac{z}{x}|x) \cdot f_X(x)dx
$$

If we want to directly work with pdf's, we will need to use the change of variable formula for multi-variables. The right formula have turns out to be

$$
\begin{aligned}
f_Z(z) = \int_0^\infty f_{X,Z}(x,z)dx &= \int_0^\infty f_{Z|X}(z|x)f_X(x)dx \\
&= \int_0^\infty f(x,\frac{z}{x}) \cdot \frac{1}{x}dx \\
&= f_{Y|X}(\frac{z}{x}|x)f_X(x) \cdot \frac{1}{x}dx
\end{aligned}
$$

As an **easier way** is to use cdf, which gives probability rather than density:

$$
\begin{aligned}
P(Z=z) &= P(XY \le z) \\
&= \int_0^\infty P(XY \le z|X=x)f_X(x)dx \qquad (\text{law of total probability}) \\
&= \int_0^\infty P(Y \le \frac{z}{x}|X=x) \cdot f_X(x)dx \\
Y|X=x \sim Exp(x) & \\
&= \int_0^\infty (1-e^{-x\cdot\frac{z}{x}}) \cdot \lambda e^{-\lambda x}dx \\
&= 1-e^{-z}\int_0^\infty \lambda e^{-\lambda x}dx \\
\Rightarrow Z \sim Exp(1) &
\end{aligned}
$$

Notation $X, Y|\{Z=k\} \overset{iid}{\sim} \cdots$ means that given $Z=k$, X and Y are *conditionally independent*, and they follow certain distribution.

(the conditional joint cdf/pmf/pdf equals the predict of the conditional cdf's/pmf's/pdf's)

3.2 Conditional expectation

We have seen that conditional pmf/pdf are legitimate pmf/pdf. Correspondingly, a conditional distribution is nothing else but a probability distributions. It is simply a (potentially) different distribution, since it takes more information into consideration.

As a result, we can define everything which are previously defined for unconditional distributions also for conditional distributions.

In particular, it is natural to define the conditional expectation.

Definition. The conditional expectation of $g(X)$ given $Y=y$ is defined as

$$\mathbb{E}(g(X)|Y=y) = \begin{cases} \sum_{i_1}^{\infty} g(x_i)P(X=x_u|Y=y) & \text{if } X|Y=y \text{ is discrete} \\ \int_{-\infty}^{\infty} g(x)f_{X|Y}(x|y)dx & \text{if } X|X=y \text{ is continuous} \end{cases}$$

Fix y, the conditional expectation is nothing but the expectation taken under the conditional distribution.
